# Effects of biomass burning emissions on the rainy season of the South America Monsoon.

O. L. Menezes, J. A. Marengo, M. M. Coutinho, T. F. Barbosa, V. B. Capistrano  
Petrópolis, RJ – Brazil  
4-6 June of 2012.

# Index

1. Introduction
2. HadGEM2-ES model
3. Hot Plume Rise scheme
4. Results
5. Conclusions

# Introduction

- Every year (from Jun. to Oct.) deforestation fires occur on the south of Amazonia and central part of South America.
- Aerosols from biomass burning are important to climate due to their impacts on radiation budget and precipitation.
- A parametrization called Hot Plume Rise (HPR) was added to HadGEM2-ES to improve the representation of emissions from biomass burning (Freitas *et al*, 2007).

# Introduction

- Known effects of high concentration of aerosols at atmosphere:
  1. Decrease of solar radiation at surface (absorption and scattering) and stabilization of boundary layer.
  2. Changes at microphysical propriety of clouds - aerosol acts as cloud condensation nuclei (CCN) and increase the number of small droplets.

# Introduction

- The aerosols can be transported far from the burning area by the winds.
- Image from MODIS at Aug of 2010.

# Introduction

From: Rosenfeld *et al*, 2008

# HadGEM2-ES model

- The UK Met Office Earth System model includes atmospheric chemistry.
- The runs are set to CMIP5, with 38 vertical levels (approx. 40km) and  $1.25^\circ$  latitude /  $1.875^\circ$  longitude.
- By default (without the HPR), products from biomass burning are vertically uniformly distributed in the boundary layer.

# Hot Plume Rise (Freitas *et al*, 2007)

- It's a 1-D cloud model within the 3-D host model column.
- The purpose of HPR is to estimate the injection layer, based on thermodynamics of the host model, where the products of burning will be released.
- This way, the products may reach heights above the boundary layer.
- The HPR was turned on based on biomass burning emissions data sets given by CMIP5.

# Results

- The following results (mostly) are the comparison between two simulations: HPR and CONTROL.
- The difference are  $HPR - CONTROL$ .

# Wind ( $m/s$ ) + Aerosols ( $kg/kg$ )

Biomass Aerosol ( $\times 1e9$ )

→ 15.0 JUN z=2000m

Biomass Aerosol ( $\times 1e9$ )

JUL z=2000m

Biomass Aerosol ( $\times 1e9$ )

AUG z=2000m

Biomass Aerosol ( $\times 1e9$ )

→ 15.0 SEP z=2000m

Biomass Aerosol ( $\times 1e9$ )

OCT z=2000m

Biomass Aerosol ( $\times 1e9$ )

NOV z=2000m

# Difference of Aerosols ( $z = 2000m$ )

Biomass Aerosol ( $\times 1e9$ )

→ 15.0 HPR-CONTROL  $z=2000m$

Biomass Aerosol ( $\times 1e9$ )

JUL HPR-CONTROL  $z=2000m$

Biomass Aerosol ( $\times 1e9$ )

AUG HPR-CONTROL  $z=2000m$

Biomass Aerosol ( $\times 1e9$ )

→ 15.0 HPR-CONTROL  $z=2000m$

Biomass Aerosol ( $\times 1e9$ )

OCT HPR-CONTROL  $z=2000m$

Biomass Aerosol ( $\times 1e9$ )

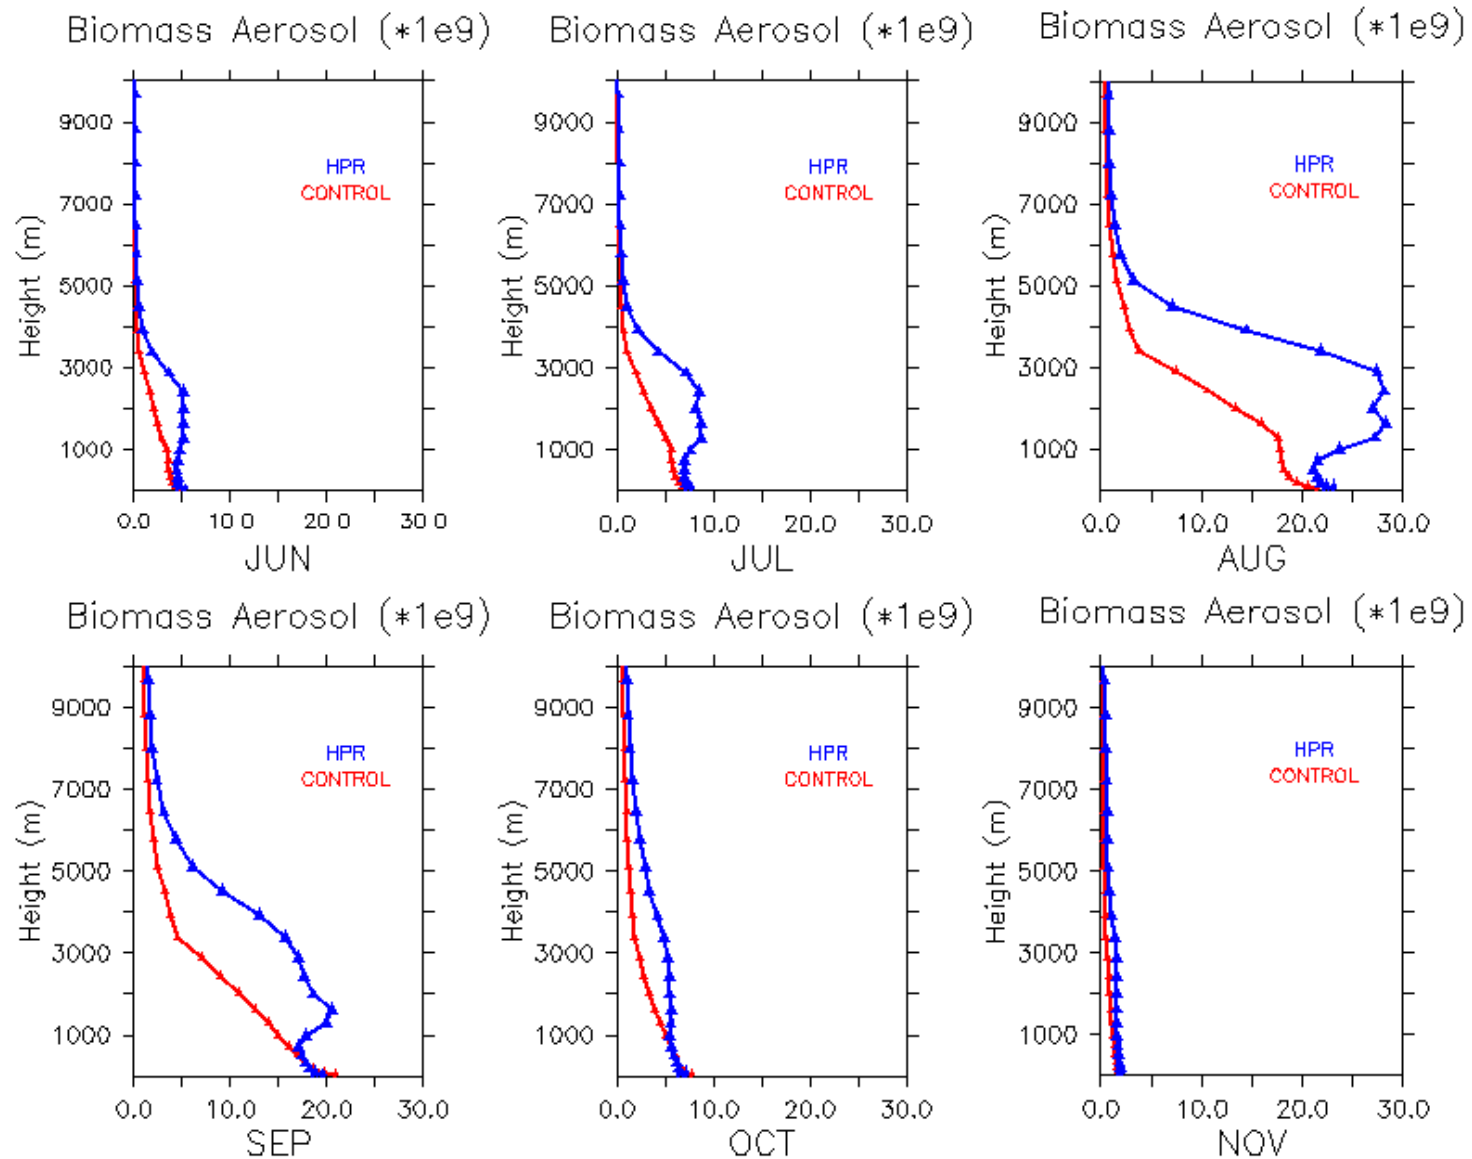

NOV HPR-CONTROL  $z=2000m$

# Aerosols and Areas of Interest

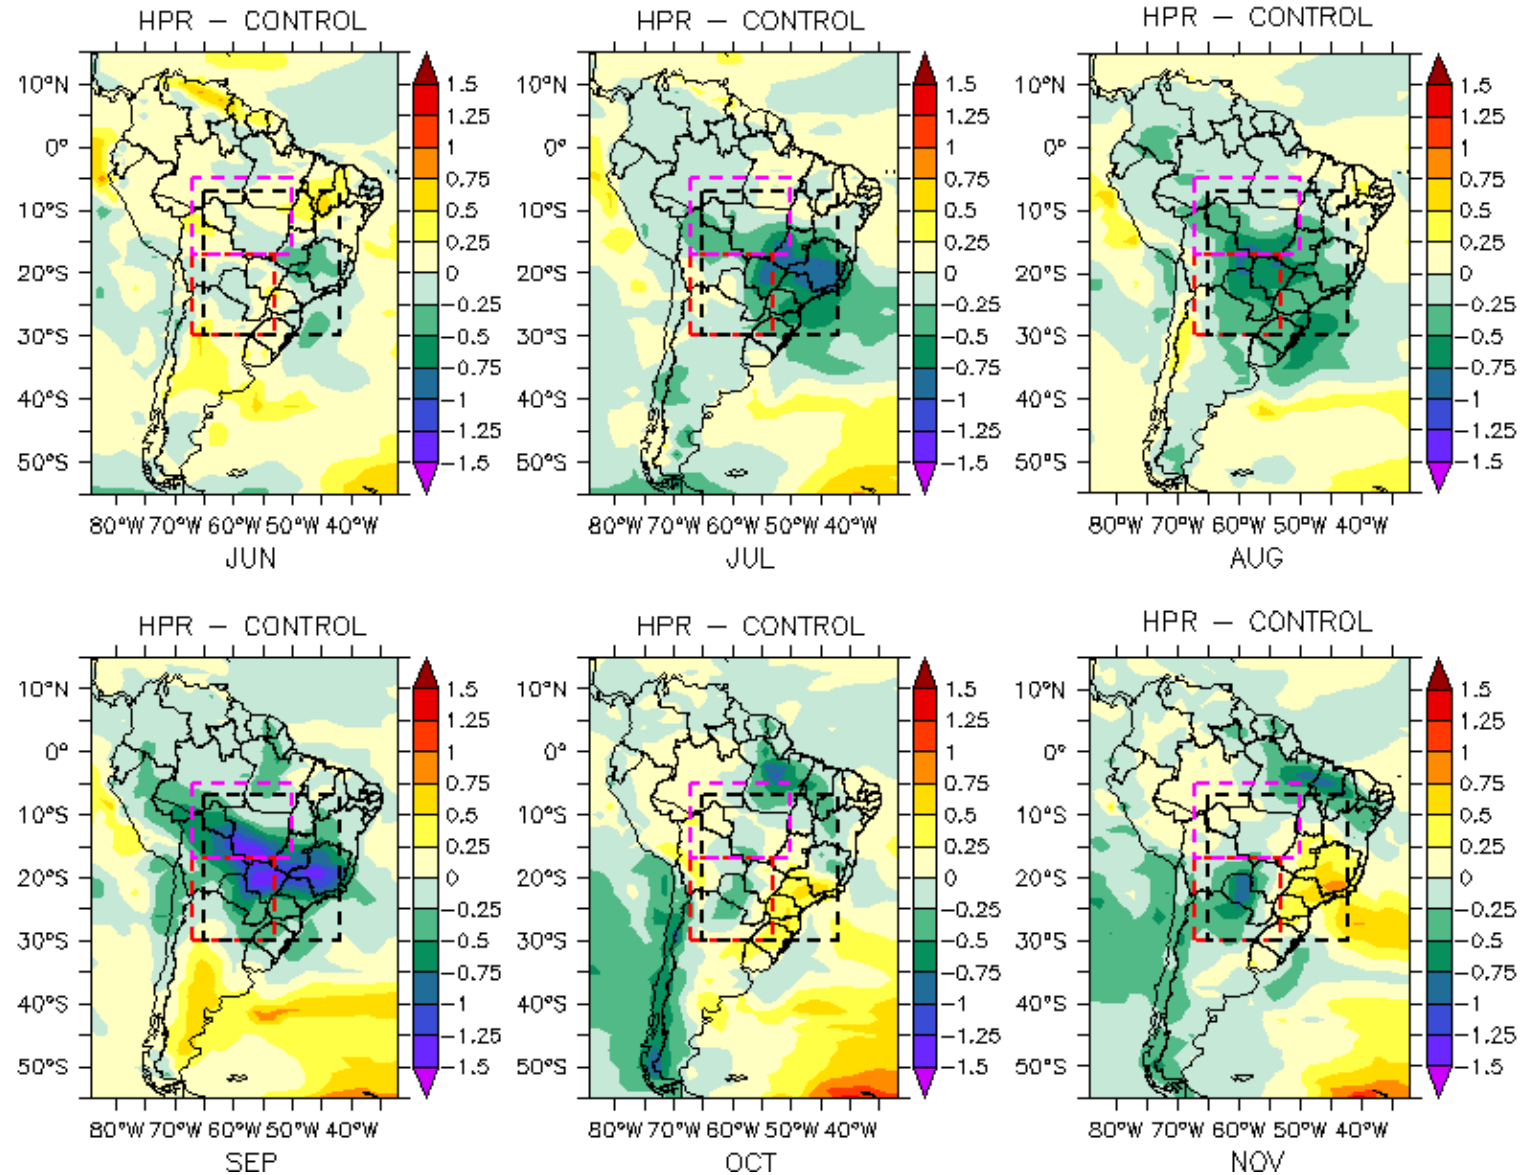

# Vertical Profile of Biomass Aerosols ( $kg/kg$ ) – Emission Zone

Emission Zone

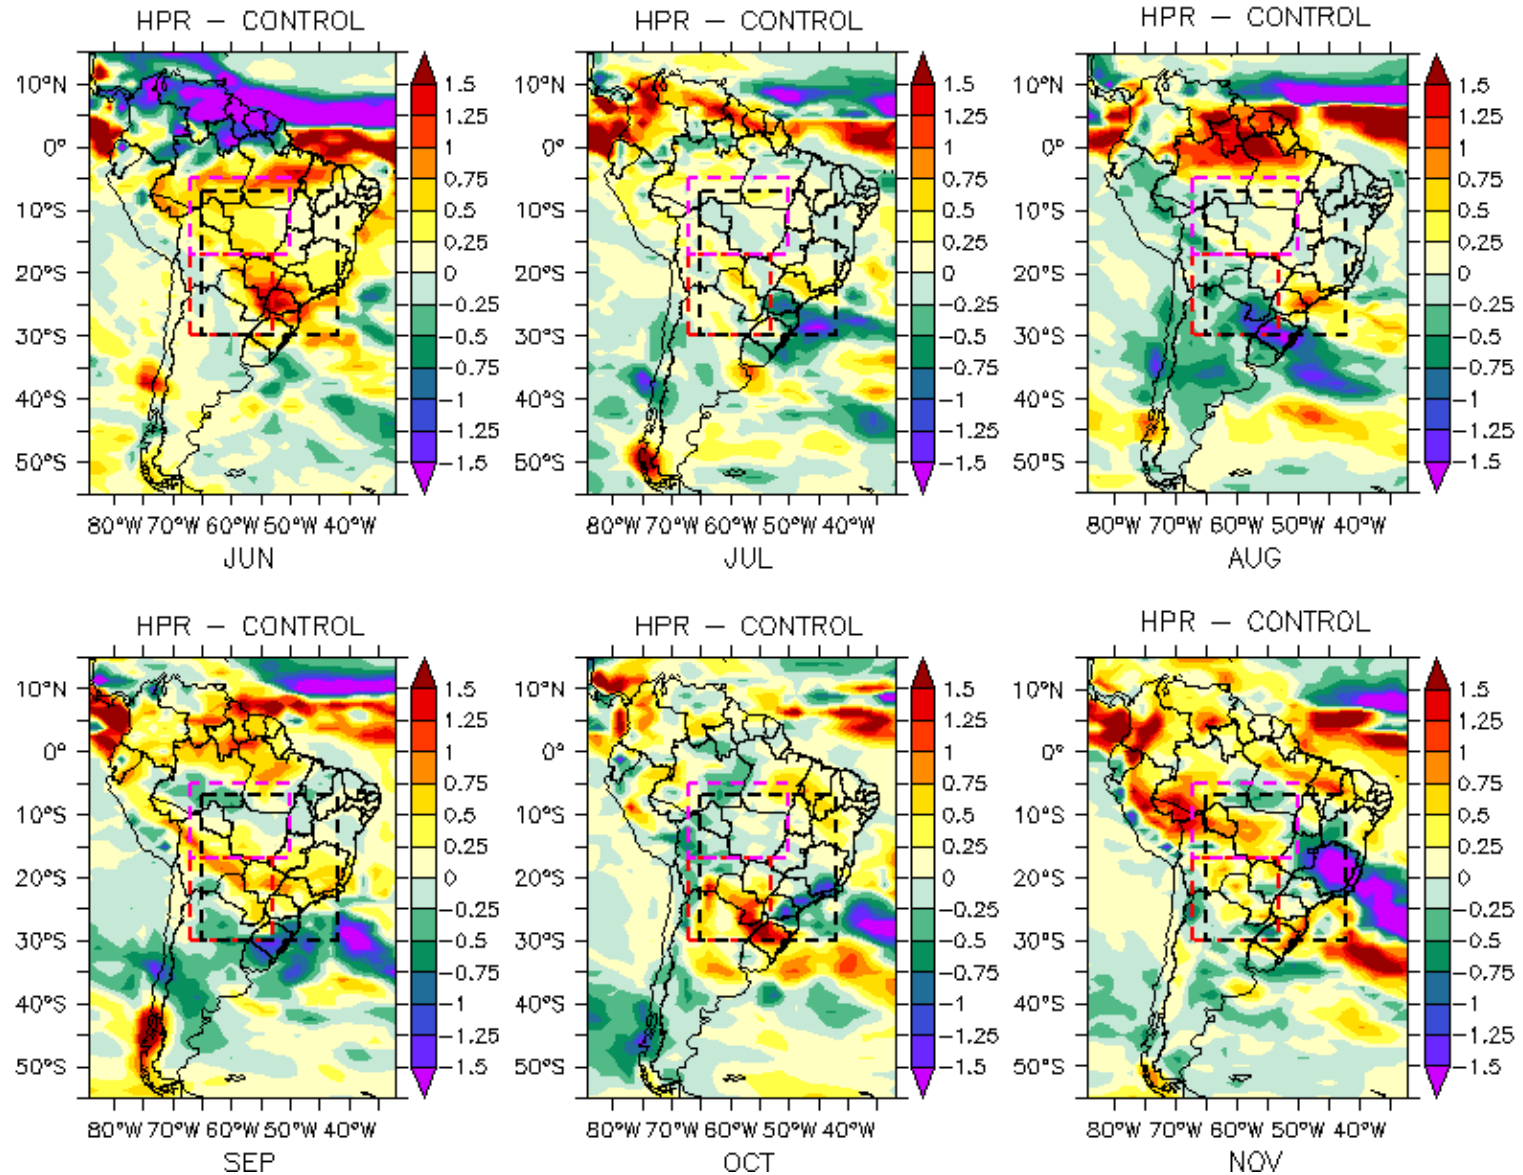

G1

# Conclusions

- The atmospheric height where the biomass burning aerosols are injected is important for their impacts on climate.
- The area that is more affected by biomass burning aerosols is G1, because it directly receives the aerosols from the Emission Zone.

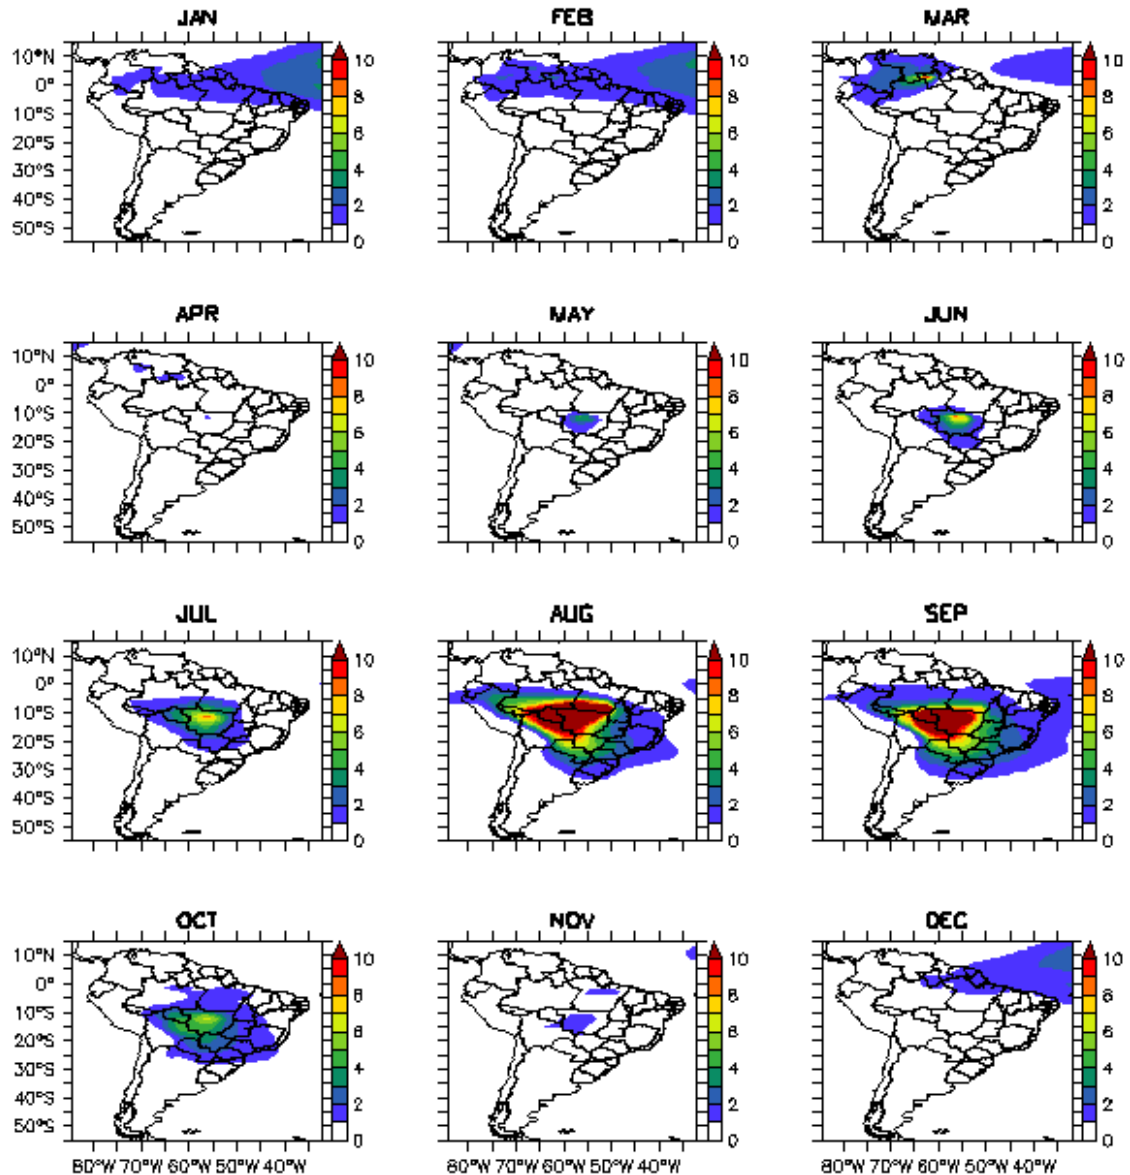

# Conclusions

- Understanding the precipitation changes is a more complex task than for temperature.
- For the area G1, the results are as follows:
- Temperature:
  - There´s a decrease of surface temperature, from Jul. to Sep.
- Precipitation:
  - There´s an increase of precipitation from Sep. to Dec.
  - August is the only month that shows a decrease of precipitation, and needs more investigation.

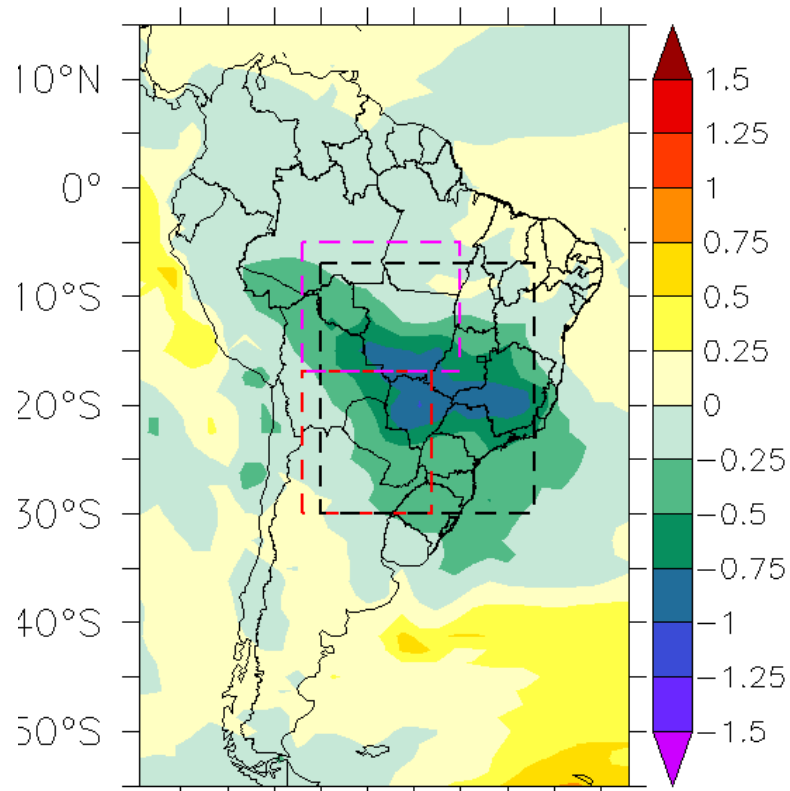

Thank you.
